(54) Title: ANTENNA SYSTEM FOR AN RF DATA COMMUNICATIONS DEVICE**(57) Abstract**

An RF data communications device antenna system (10) is shown that includes a dipole and an electromagnetic coupler (16) that provides coupling between each dipole arm (22, 24) to establish a desired resonant bandwidth. An LC matching circuit (30) is provided for matching the dipole to the impedance of the RF data communications device and for transforming the RF signal between the dipole arms of the antenna system.

ANTENNA SYSTEM FOR AN RF DATA COMMUNICATIONS DEVICE

Background of the Invention

5

The present invention is directed to the field of antennae used for RF data communications devices, particularly those used to transmit and receive digital signals, e.g. two-way pagers and the like. There has been a proliferation in recent years in the field of RF telecommunications with items such as cordless and cellular telephones becoming commonplace items. Pagers, in particular, have become common among individuals who need to be quickly contacted from remote locations, e.g. technicians, etc. With such devices, it is very important to maintain a clear, strong signal that preserves the integrity of the data transmission.

The antennae used with previous RF data communication devices are prone to many significant problems. Some devices, such as pagers are usually worn on the person of the user. However, the human body has certain inherent dielectric properties (e.g. due to charge and current fluctuations, etc.) that create an electromagnetic boundary. The inherent boundary conditions of the body of the user changes the surrounding impedance, affecting the

-2-

antenna current distribution and the signal radiation pattern, thus lowering the gain of the antenna by about 4dB. In this way, the antenna is "detuned." Antenna detuning is also caused by the
5 presence of certain objects (e.g. metallic bodies) and also various ground plane conditions. This effect results in a shorter operating radius and poor in-building performance for RF data communications devices, especially pagers.

10 Previous devices also suffer from performance problems related to the polarization characteristics of the transmission and reception signals. Electromagnetic radiation propagates in any plane and can thus be regarded as having
15 vertical and horizontal polarizations. In order to receive a strong signal, an antenna must be properly aligned with the polarization plane of the incoming signal. However, when a device is in operation, it may be turned in all different directions and may
20 not be optimally aligned to receive an incoming signal. In a two-way device, a similar problem results in transmission from the device. Previous device antennae incorporate a loop design, which is nominally effective at implementing the two
25 polarizations but suffers from low gain and low bandwidth. Environmental sources also affect the

-3-

reception of a polarized signal. For example, the metal in buildings effectively "tips" a vertically polarized wave, thus weakening the strength of a signal received with a vertically polarized antenna.

5 One method of addressing the above-noted limitations imposed by signal reception in an RF data communications device, such as a pager, is to establish two-way communication, so that an acknowledgment or reply signal is transmitted from
10 the pager back to the source. However, because these devices are usually worn or used in close proximity to the user's body, the electromagnetic boundary around the user's body also sharply reduces transmission efficiency. Also, transmission
15 bandwidths as low as 1/2% are typical with previous two-way pagers. In these ways, the antennae of previous RF data communications devices do not provide the reliable and efficient operation necessary for the transmission and reception of a
20 digital signal.

Summary of the Invention

In view of the difficulties and drawbacks associated with previous antennae for RF data
25 communication devices, it would be advantageous to provide an antenna system that solves the previous

-4-

problems by implementing a more reliable and efficient antenna design.

Therefore, there is a need for an improved antenna system that provides an RF data
5 communications device with an increased operating radius.

There is also a need for a for an improved antenna system that provides a two-way data communication device with improved in-building
10 performance.

There is also a need for an antenna system that renders an RF data communications device less sensitive to environmental fluctuations.

There is also a need for an antenna system
15 that enables an RF data communications device to operate with less sensitivity to directional position.

There is also a need for an RF data communications device that provides stable, high
20 gain, two-way data communication.

There is also a need for a antenna system that permits simultaneous transmission and receipt of data in an RF data communications device.

There is also a need for a method of
25 improving transmission and reception through an

-5-

antenna system used in conjunction with an RF data communications device.

These needs and others are realized by the antenna of the present invention, which preferably
5 includes a dipole having two substantially orthogonal elements for receiving and transmitting an electromagnetic signal. An electromagnetic coupling is used to balance the signal strength between each dipole element to establish a desired
10 resonant bandwidth. An impedance matching circuit, preferably in the form of an LC lumped matching circuit is provided including at least one capacitor and at least one inductor for electrically connecting the dipole to the data communications
15 device.

As will be appreciated, the invention is capable of other and different embodiments, and its several details are capable of modifications in various respect, all without departing from the
20 invention. Accordingly, the drawings and description are to be regarded as illustrative in nature and not restrictive.

Brief Description of the Drawings

25 The embodiments of the invention will now be described by way of example only, with reference

-6-

to the accompanying figures wherein the members bear like reference numerals and wherein:

Fig. 1a shows a hand-held data communications device having a single antenna as
5 according to the present invention.

Fig. 1b shows an alternative embodiment of a hand-held data communications device having dual antennae as according to the present invention.

Fig. 2 illustrates the configuration and
10 operation of the antenna of the present invention.

Fig. 3 shows the detail of the matching circuit as according to the present invention.

Figs. 4A and 4B show respectively the amplitude and spatial response for an under-coupled
15 and critically-coupled dipole antenna, as according to the present invention.

Figs. 5A and 5B show respectively the amplitude and spatial response for an over-coupled dipole antenna, as according to the present
20 invention.

Figs. 6A and 6B show respectively a single antenna and dual antenna configuration of an RF data communications device incorporating the present invention.

-7-

Figure 7A is a diagram of an RF data communications device utilizing a single antenna configuration according to the present invention.

Figure 7B is a diagram of a RF data
5 communications device utilizing a dual antenna configuration according to the present invention.

Detailed Description of the Invention

Referring now to the drawings, which are for purposes of illustrating only preferred
10 embodiments of the present invention and not for purposes of limiting the same, the figures show one embodiment of the invention wherein a single dipole antenna having an electromagnetic coupling and an LC impedance matching circuit that provides an
15 unbalanced to balanced transformation. A second embodiment illustrating the use of a dual antenna configuration is also shown. The antenna, whether alone or as part of a dual antenna configuration, is especially suited for transmitting and receiving in
20 a range of 800-1000 Mhz, although it will be appreciated by one of ordinary skill in the art that the antenna can be constructed so as to operate at other frequency ranges.

Fig. 1a shows, by way of example of the
25 preferred embodiment of the invention, a device 10, such as a pager, incorporating an antenna as

-8-

according to the present invention. In its preferred embodiment, the device includes a lid 12 and a body 14. The lid 12 preferably includes an LCD display 16 for displaying both incoming and outgoing alphanumeric data. The body 14 receives and retains the electronic components that process the device signal and provide other device functions. Antenna 20 is preferably incorporated into the device lid 14 and thus hidden from view. Figure 1b shows two antennae 30 in a configuration designed for either simultaneous transmission and reception of data or to reduce the design requirements imposed by a single antenna structure.

As shown in Figs. 1a, 1b and 2, the preferred construction of antenna 20 is a dipole formed of a horizontal arm 22 and a vertical arm 24 for receiving the signal in each of the vertical and horizontal polarization planes. The respective dipole arms 22, 24 are sized to fit within the device lid 12, and in the case of the dual antenna configuration, are placed in such a manner that each antenna 30 is conductively isolated from the other. The arms 22, 24 are preferably made of copper and have a thickness of about 0.0025" on a 0.001" Kapton material substrate. The horizontal arm 22 is preferably about 2.04" in length with an extending

-9-

portion of about 0.54". The vertical arm 24 is preferably about 2.17" long, with a lower portion about 1.19" in length. In the preferred embodiment, the horizontal arm and the vertical arm
5 are substantially orthogonal, i.e. they form a substantially 90° angle. As one of ordinary skill in the art will appreciate, however, the position of the arms need only to be at an angle such that the two arms are not in the same line. Since antenna 20
10 is two-dimensional in shape, it can transmit and receive signals in both planes of polarization (as shown in Fig. 2), thus enabling a device, such as a device to be less sensitive to tilting and orientation and to provide excellent in-building
15 performance. The preferred construction of dipole antenna 20 results in a gain of about 0dB at 900MHz, at least a 5dB improvement in gain over the previous loop-type antenna frequently used in pagers.

In a single antenna configuration, the
20 data signal is reciprocally processed through an LC lumped matching circuit 30, as shown in Fig. 3, that preferably includes capacitors (C1, C2) and inductors (L1, L2, L3) for connecting the dipole arms 22, 24 to a coaxial cable within the device
25 body 14. In the preferred embodiment for operating in the 900 Mhz frequency range, C1 = 4.3pF, C2 =

-10-

7.5pF, $L1 = L2 = 3.9\text{nH}$ and $L3 = 4.7\text{nH}$; the coaxial cable is a MXFX81 cable and display 16, which also can affect the values of $C1$, $C2$, $L1$, $L2$ and $L3$, is preferably a FSTN LCD available from Varitronix, 5 Hong Kong as part no. CRUS 1024-V05. For any given data communications device, the internal impedance of the device can be directly measured and the values for $C1$, $C2$, $L1$, $L2$ and $L3$ can be calculated empirically from that measurement. LC circuit 30 10 provides transformer action, matching action and balancing action, as will be shown subsequently.

LC circuit 30 provides an impedance to antenna 20 to match the 50 ohm impedance of the RF device contained within device body 14. This 15 impedance matching reduces currents induced on the device components by the presence of a human operator and various ground plane conditions, thereby improving the gain of the device.

The present matching circuit also provides 20 a transformer action wherein the signal energy is proportioned between each of the arms. In a transmission mode, an RF signal is fed through a coaxial cable 32 into the circuit 30 where it is split into each of the arms 22, 24 where the signal 25 is transformed to electromagnetic radiation which propagates through the air. In the receiving mode,

-11-

the matching circuit 30 combines the signals received and transforms the RF signal to a detectable level. The detectable signal then travels through the coaxial cable to the RF data communications device.

The performance of the present antenna is greatly facilitated by the coupling between the dipole arms 22, 24. Applicants have discovered that the presence of an anisotropic medium in proximity with the antenna is effective at controlling the electrical environment within the device and affecting the propagation vector of the antenna. The liquid crystal material in the present LCD 16 is anisotropic, and as applicants have discovered, its anisotropic nature provides the desired coupling properties. As used herein, the present "coupling" is analogous to the mutual inductance in a transformer, where electromagnetic energy propagates across a pair of the inductors in respective resonating circuits.

By carefully positioning the two dipole arms, the feed cable and the LCD 16, applicants have discovered that the two dipole arms 22, 24 can be electromagnetically coupled as are the inductors in a transformer. The anisotropic material of the LCD 16 creates a non-uniform electric field effectively

-12-

splitting the signal transmitted and received from each dipole element into perpendicular components. The signal propagated from the horizontal dipole 22 propagates in a horizontal polarization. However, a
5 portion of the signal propagating through the LCD 16 is transformed into the vertical polarization, so that the original polarized wave is effectively split into waves having vertical and horizontal polarization. Similarly, the polarized signal
10 propagating from the vertical dipole 24 is split into perpendicular components. The electromagnetic coupling through the LCD 16 is such that each of these respective perpendicular components reinforce each other in phase, so that constructive wave
15 fronts are produced for each polarization. In this way, each of the respective dipoles 22, 24 are electromagnetically coupled.

Under-coupling of the dipoles occurs when the mutual effects of each dipole element on the
20 respective other produce a single resonant amplitude peak. Critical-coupling results in a single resonant mode with maximum amplitude about a central frequency. The resonant response of under-coupled and critically-coupled antennae is shown in Fig. 4A.
25 These couplings also result in a spatial amplitude peak as shown in Fig. 4B., in which antenna gain

-13-

peaks around 230 degrees (where zero is the forward facing direction of the user.)

Antenna performance as according to the preferred embodiment occurs when coupling is further

5 increased so that the dipole becomes overcoupled. The resonant amplitude of an overcoupled dipole resonates at two peak frequencies of equal amplitude, with respective peaks representing the symmetrical and antisymmetrical modes centered about

10 a desired base frequency, as shown in Fig. 5A. This results in an effectively broadened resonant frequency bandwidth. Also, the frequency peaks are birefringent, i.e., each has a propagation vector perpendicular to the other. The overcoupled dipole

15 thus propagates two perpendicular signals differing only slightly in resonant symmetrical and antisymmetrical frequency. The result is an antenna with a broadened effective bandwidth in both polarizations, thus increasing the antenna gain.

20 The overcoupled dipole also resonates with two spatial amplitude peaks, as seen in Fig. 5B. The gain is thus higher over a larger perimeter of the user, and therefore the present antenna is less sensitive to directional variations in gain.

25 Dipole 20 and matching circuit 30 cooperate to enable a two-way RF data communications

-14-

device that is stable and insensitive against antenna detuning in the ambient environment. Antenna detuning can occur from, among many causes, parasitic capacitance and adverse ground plane conditions. Also, the present invention is insensitive to directional orientation and signal deflections within buildings. The present invention offers at least a 5dB improvement in gain over previous loop antennae and at least a 3db improvement in gain over patch antennae used in hand-held data communications devices and an operative bandwidth at about 10% as compared with 1-2% for other one-way devices and 1/2% for other two-way devices.

Turning now to Figs. 6A and 6B, shown are two implementations of the invention in conjunction with an RF data communications device. Figure 6A shows a simple block diagram of an RF data communications device, such as a pager, which incorporates the instant invention. Such a device would include a control subsystem 200 comprising a DSP 130, memory 140 and control 150; a radio receiver 110 and a radio transmitter 120; and the antenna system 170 of the instant invention comprising a dipole antenna 20 in conjunction with a matching circuit, and LCD display 16 that, as discussed above, serves the dual

-15-

function of displaying data as a part of data interface 160 and as an anisotropic medium for electromagnetic coupling of the signals radiating from the arms of the dipole antenna 20.

5 Switch/Duplexer 175 represents the element that places the antenna system 170 in either a transmit or receive mode. Although shown as part of antenna system 20, switch/duplexer 175 could just as easily be represented and configured as an element that
10 functions outside antenna system 20, but operatively connected to it. Figure 7A, discussed in greater detail below, illustrates the placement of the switch/duplexer 175 outside the antenna subsystem. Additionally, the function that switch/duplexer 175
15 performs could be performed with a electronic, software or mechanical switch, or a duplexer or by any means by which different data streams, one in-bound and one out-bound can be separated and either transmitted or received, as relevant, over the
20 dipole antenna 20.

Figure 6B differs from Figure 6A only in its use of a dual antenna system 171. Receive antenna 28 and transmit antenna 29 replace the single dipole antenna 20 to enable the RF data
25 communications device to transmit and receive simultaneously or to reduce the design requirements

-16-

associated with a single antenna configuration.
This configuration eliminates the need for the
switch/duplexer 175 found in Figure 6, because each
mode is accommodated by a separate antenna in this
5 configuration.

Figures 7A and 7B are more detailed
versions of the RF communications devices shown in
Figures 6A and 6B, respectively. Antenna 20 and
Display 16 are represented in Antenna/Display
10 Subsystem 600. Radio Receiver 110 is represented by
items 111-117, IQ demodulator 118, auxiliary local
oscillator synthesizer 119 and local oscillator
synthesizer 200, which Radio Receiver 110 shares
with Radio Transmitter 120. Radio Transmitter 120
15 includes items 311-314, 321-324, 330-336, clock
circuit 210, and local oscillator synthesizer 200,
which it shares with Radio Receiver 110. Memory 140
is represented by flash RAM 141 and SRAM 142.
Control 150 is represented by microprocessor 500 in
20 conjunction with control line 151. Data Interface
is represented by serial line 161 in conjunction
with microprocessor 500. As previously mentioned,
display 16 could also be consider part of the data
interface 160. Additionally, any input device, such
25 as a keyboard, mouse, touchscreen, etc., would be
considered part of data interface 160.

-17-

In addition to the above items, Figures 7A and 7B illustrate other components of the RF data communications device. Items 601 and 602 represent the circuitry for processing data from Battery
5 Voltage Sensor 603. Items 701 and 702 represent the circuitry for processing data from Temperature Sensor 703. Also included in the device is Power Management Circuitry 100.

Figure 7B differs from Figure 7A only in that
10 it includes a dual antenna configuration represented by Receive Antenna 28 and Transmit Antenna 29. As a result, switch/duplexer 175 comprising T/R switch 176 is no longer needed. It should be noted, however, that because the receive circuit and the
15 transmit circuit share Local Oscillator Synthesizer 200, it is not possible for this device to utilize the dual antenna structure to transmit and receive simultaneously. By replicating the functions that are share by including an additional local
20 oscillator synthesizer, one can easily see that the use of dual antennae would enable, in that instance, simultaneous transmission and reception.

As described above, the present invention solves many problems associated with previous
25 antennae used with RF data transmission and presents improved efficiency and operability. Although the

-18-

preferred embodiment of the invention has been described in reference to a pager, the invention has applicability to any device that has the need for an antenna system that solves many problems found in

5 prior art antennae. Without limiting the generality of the instant invention, it should be noted that among the devices to which the antenna system of the instant invention can be applied are notebook computers, combined cell phones and pagers, PDA's,

10 PIM's and other personal data devices, including those worn on the wrist, in conjunction with eyeglasses or as a belt around the body.

Additionally, it will be appreciated that various changes in the details, materials and arrangements

15 of parts which have been herein described and illustrated in order to explain the nature of the invention may be made by those skilled in the art within the principle and scope of the invention as expressed in the appended claims.

-19-

We Claim:

1. An antenna system for enhancing the performance of an RF data communications device comprising:

5 a dipole having a first arm extending in a first direction and a second arm extending in a second direction that is not in the same line as the first direction ;

an electromagnetic coupler, wherein the
10 electromagnetic coupler balances the signal strength between the first arm and the second arm and establishes a desired resonant bandwidth for operating the RF data communications device; and
an impedance matching circuit including at
15 least one capacitor element and at least one inductor element, wherein the matching circuit matches the impedance of the RF data communications device to which the antenna is operatively connected.

20 2. The antenna system of claim 1 wherein the electromagnetic coupler comprises an anisotropic medium placed in proximity to the dipole.

3. The antenna system of claim 2 wherein the anisotropic medium comprises a liquid crystal
25 display.

-20-

4. The antenna system of claim 1 wherein the matching circuit is a lumped L.C. circuit

5. The antenna system of claim 4 wherein the values of each inductor and each capacitor are
5 selected to provide impedance matching and a balanced to unbalanced transformation between the dipole and the RF data communications device.

6. The antenna system of claim 1, wherein the dipole is a first dipole and wherein the antenna
10 system further comprises a second dipole placed in proximity to the first dipole and to the electromagnetic coupler.

7. An RF data communications device with improved antenna performance comprising:

15 a data interface;
a radio receiver and
a radio transmitter, wherein the data interface, radio receiver and radio transmitter are connected through a microprocessor; and
20 an antenna system, wherein the antenna system comprises:

a dipole having a first arm extending in a first direction and a second arm extending in a second direction that is not in the same line as the
25 first direction;

-21-

an electromagnetic coupler, wherein the electromagnetic coupler balances the signal strength between the first arm and the second arm and establishes a desired resonant bandwidth for
5 operating the RF data communications device; and

an impedance matching circuit including at least one capacitor element and at least one inductor element, wherein the matching circuit matches the impedance of the RF data communications
10 device to which the antenna is operatively connected.

8. The RF data communications device of claim 7, further comprising a transmit/receive switch, wherein the switch switches the mode of the
15 antenna system from transmission to reception and from reception to transmission, the dipole is used for transmitting when the switch has switched the mode of the antenna system to transmission and the dipole is used for receiving when the switch has
20 switched the mode of the antenna system to reception.

9. The RF data communications device of claim 8, wherein the transmit/receive switch is a duplexer.

25 10. The RF data communications device of claim 7, wherein the dipole is a first dipole and

-22-

wherein the antenna system further comprises a second dipole placed in proximity to the first dipole and to the electromagnetic coupler.

11. The RF data communications device of
5 claim 10, wherein RF signal reception occurs through the first dipole and RF signal transmission occurs through the second dipole.

12. A method of enhancing performance of
an antenna associated with an RF data communications
10 device comprising the steps of:

placing an anisotropic medium between two
arms of a dipole antenna; and

energizing the anisotropic medium and the
dipole antenna so as to split signals radiating from
15 each dipole antenna arm into orthogonal components
to create a desired resonant bandwidth.
